Quantifier Operations

Quantifier Operations

✓ Quantifier operations are used on a data source to check If some or all elements of that data source satisfy a condition or not.

✓ All the methods in quantifier operations return a Boolean value.

✓ Condition may be for some or all the elements.

Quantifier Operations Examples

✓ We need to check whether all the students of a class are present or not.

✓ In a class of students we need to check if any student has number more than 80%.

✓ We need to check if a class of students has any student with name Bob.

✓ Etc...

Quantifier Operations Methods

✓ **All** (Whether all elements of a data source satisfy a condition)

✓ **Any** (Whether at least one element of a data source satisfy a condition)

✓ **Contains** (Check whether data source contains a specified element)
